

## Results

An independent sample *t*-test was used to test the amount of assistance the child needed to perform a series of activities and parental involvement. There was no significant main effect across variables; indicating there were no significant differences regarding child assistance ( $M = 7.68$ ;  $SD = 2.68$ ) with the amount of parental involvement ( $M = 6.55$ ;  $SD = 1.81$ ),  $t(31) = 1.27$ ,  $p = .215$  (2-tailed). From this table, Response 1 shows that participants needed additional help upon completion of the first activity, but in correlation to Response 2 there was no significant difference between means. Moreover, no significant difference was found between *t*-strings, although Response 2 was more consistent due to having a smaller standard deviation. See Table 1 for results.

**Table 1**

*Statistics of necessary assistance required and parental involvement.*

Pair	Mean	SD	<i>t</i>
Response 1	7.68	2.68	1.27
Response 2	6.55	1.81	1.44

*Note: \*  $p > .05$ . \*\*  $p > .001$ .  $df = 31$ .*
