

Pearson Correlation

A Pearson Correlation was done to determine the correlation between a parent's level of involvement in an activity with their child, and the willingness to complete a similar activity again in the future. The variables were operationalized by using the following questions, "What was your level of involvement in the activity with your child?" and "How willing would you be to do Family Fun Time activities like this one in the future?" Both of these questions used a 0 to 10 scale, with 0 being "not at all," and 10 being "a great amount." The result of the Pearson Correlation, $-.043$, indicates that there is no significant correlation between the two variables selected for analysis.
